Recurrent Neural Networks

Latest Submission Grade 100%

---

1. Suppose your training examples are sentences (sequences of words). Which of the following refers to the jth word in the ith training example?

1 / 1 point

◉ $x^{(i)<j>}$

◯ $x^{<i>(j)}$

◯ $x^{(j)<i>}$

◯ $x^{<j>(i)}$

✓ **Correct**
We index into the ith row first to get the ith training example (represented by parentheses), then the jth column to get the jth word (represented by the brackets).

---

2. Consider this RNN:

1 / 1 point

This specific type of architecture is appropriate when:

◉ $T_x = T_y$
◯ $T_x < T_y$

◯ $T_x > T_y$

◯ $T_x = 1$

✓ **Correct**
It is appropriate when every input should be matched to an output.

---

3. To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply).

1 / 1 point

$\hat{y}$
▲

$a^{<0>} \rightarrow \square \rightarrow \square \rightarrow \cdots \rightarrow \square$

$x^{<1>}$ $x^{<2>}$ $x^{<T_x>}$

☐ Speech recognition (input an audio clip and output a transcript)

☑ Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)

✓ **Correct**
Correct!

☐ Image classification (input an image and output a label)

☑ Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender)

✓ **Correct**
Correct!

**4.** You are training this RNN language model.

1 / 1 point

$\hat{y}^{<1>}$ $\hat{y}^{<2>}$ $\hat{y}^{<T_y>}$

$a^{<0>} \rightarrow \square \rightarrow \square \rightarrow \cdots \rightarrow \square$

0 $y^{<1>}$ $y^{<T_y-1>}$

At the tth time step, what is the RNN doing? Choose the best answer.

○ Estimating $P(y^{<1>}, y^{<2>}, \ldots, y^{<t-1>})$

○ Estimating $P(y^{<t>})$

◉ Estimating $P(y^{<t>} \mid y^{<1>}, y^{<2>}, \ldots, y^{<t-1>})$

○ Estimating $P(y^{<t>} \mid y^{<1>}, y^{<2>}, \ldots, y^{<t>})$

✓ **Correct**
Yes, in a language model we try to predict the next step based on the knowledge of all prior steps.

5. You have finished training a language model RNN and are using it to sample random sentences, as follows:

1 / 1 point

$\hat{y}^{<1>}$ $\hat{y}^{<2>}$ $\hat{y}^{<3>}$ $\hat{y}^{<T_y>}$
What are you doing at each time step t?

○ (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{<t>}$. (ii) Then pass the ground-truth word from the training set to the next time-step.

○ (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{<t>}$.(ii) Then pass the ground-truth word from the training set to the next time-step.

○ (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{<t>}$.(ii) Then pass this selected word to the next time-step.

◉ (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{<t>}$.(ii) Then pass this selected word to the next time-step.

✓ **Correct**

---

6. You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem?   **1/1 point**

○ Vanishing gradient problem.

◉ Exploding gradient problem.

○ ReLU activation function g(.) used to compute g(z), where z is too large.

○ Sigmoid activation function g(.) used to compute g(z), where z is too large.

✓ **Correct**

---

7. Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations $a^{<t>}$. What is the dimension of Γ_u at each time step?   **1/1 point**

○ 1

◉ 100

○ 300

○ 10000

✓ **Correct**
Correct, Γ_u is a vector of dimension equal to the number of hidden units in the LSTM.

---

8. Here're the update equations for the GRU.   **1/1 point**

GRU

$$\tilde{c}^{<t>} = \tanh(W_c[\Gamma_r * c^{<t-1>}, x^{<t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{<t-1>}, x^{<t>}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{<t-1>}, x^{<t>}] + b_r)$$

$$c^{<t>} = \Gamma_u * \tilde{c}^{<t>} + (1 - \Gamma_u) * c^{<t-1>}$$

$$a^{<t>} = c^{<t>}$$

Alice proposes to simplify the GRU by always removing the Γ_u. I.e., setting Γ_u = 1. Betty proposes to simplify the GRU by removing the Γ_r. I. e., setting Γ_r = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

○ Alice's model (removing Γ_u), because if $\Gamma_r \approx 0$ for a timestep, the gradient can propagate back through that timestep without much decay.

○ Alice's model (removing Γ_u), because if $\Gamma_r \approx 1$ for a timestep, the gradient can propagate back through that timestep without much decay.

◉ Betty's model (removing Γ_r), because if $\Gamma_u \approx 0$ for a timestep, the gradient can propagate back through that timestep without much decay.

○ Betty's model (removing Γ_r), because if $\Gamma_u \approx 1$ for a timestep, the gradient can propagate back through that timestep without much decay.

✓ **Correct**
Yes. For the signal to backpropagate without vanishing, we need $c^{<t>}$ to be highly dependent on $c^{<t-1>}$.

---

9. Here are the equations for the GRU and the LSTM: **1/1 point**

GRU

$$\tilde{c}^{<t>} = \tanh(W_c[\Gamma_r * c^{<t-1>}, x^{<t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{<t-1>}, x^{<t>}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{<t-1>}, x^{<t>}] + b_r)$$

$$c^{<t>} = \Gamma_u * \tilde{c}^{<t>} + (1 - \Gamma_u) * c^{<t-1>}$$

$$a^{<t>} = c^{<t>}$$

LSTM

$$\tilde{c}^{<t>} = \tanh(W_c[a^{<t-1>}, x^{<t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[a^{<t-1>}, x^{<t>}] + b_u)$$

$$\Gamma_f = \sigma(W_f[a^{<t-1>}, x^{<t>}] + b_f)$$

$$\Gamma_o = \sigma(W_o[a^{<t-1>}, x^{<t>}] + b_o)$$

$$c^{<t>} = \Gamma_u * \tilde{c}^{<t>} + \Gamma_f * c^{<t-1>}$$

$$a^{<t>} = \Gamma_o * c^{<t>}$$

From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to _____ and _____ in the GRU. What should go in the blanks?

◉ Γ_u and $1 - \Gamma_u$

○ Γ_u and Γ_r

○ $1 - \Gamma_u$ and Γ_u

○ Γ_r and Γ_u

✓ **Correct**
Yes, correct!

---

10. You have a pet dog whose mood is heavily dependent on the current and past few days' weather. You've collected data for the past 365 days on the weather, which you represent as   **1/1 point**
a sequence as $x^{<1>}, \ldots, x^{<365>}$. You've also collected data on your dog's mood, which you represent as $y^{<1>}, \ldots, y^{<365>}$. You'd like to build a model to map from $x \to y$. Should you use a Unidirectional RNN or Bidirectional RNN for this problem?

○ Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information.

○ Bidirectional RNN, because this allows backpropagation to compute more accurate gradients.

○ Unidirectional RNN, because the value of $y^{<t>}$ depends only on $x^{<1>}, \ldots, x^{<t>}$, but not on $x^{<t+1>}, \ldots, x^{<365>}$

○ Unidirectional RNN, because the value of $y^{<t>}$ depends only on $x^{<t>}$, and not other days' weather.

✓ **Correct**
   Yes!
